

# Evaluating Regression and Classification (Performance evaluation)

# Introduction

- We will explore how to measure how well a model works for predicting numbers (**regression**) and categories (**classification**).
- **Example:** Predicting milk yield (**regression**) and whether a cow is "High" or "Low" yielding (**classification**).

# Loading the Data

- We first load our dataset from a file called “Animal\_data.csv”.
- Think of this like opening a spreadsheet that has animal details and results.

Train model and predict the same data

| Obj | X1 | X2 | X3 | Y  |
|-----|----|----|----|----|
| 1   | 4  | 9  | 4  | 20 |
| 2   | 8  | 4  | 6  | 11 |
| 3   | 1  | 5  | 7  | 12 |
| 4   | 3  | 3  | 7  | 11 |
| 4   | 2  | 4  | 8  | 23 |
| 5   | 4  | 5  | 4  | 11 |
| 6   | 5  | 6  | 5  | 22 |
| 7   | 6  | 4  | 3  | 23 |
| 8   | 5  | 5  | 4  | 31 |
| 9   | 6  | 6  | 3  | 22 |
| 10  | 6  | 7  | 6  | 16 |
| 11  | 7  | 7  | 6  | 25 |
| 12  | 8  | 8  | 8  | 33 |

Predict

| Y-pred |
|--------|
| 18     |
| 9      |
| 13     |
| 12     |
| 20     |
| 8      |
| 22     |
| 24     |
| 30     |
| 21     |

| 34     |

# Leave one out and fold cross-validation

- We split data into  $K$  groups.
- Train on  $K-1$  groups, test on the remaining group.
- Repeat  $K$  times so each group gets tested.
- Average results = fairer measure of model accuracy.

## Training (11) and leave one out cross-validation (1)

Training  
data

Test on number 12

| No | X1 | X2 | X3 | Y  |
|----|----|----|----|----|
| 1  | 4  | 9  | 4  | 20 |
| 2  | 8  | 4  | 6  | 11 |
| 3  | 1  | 5  | 7  | 12 |
| 4  | 3  | 3  | 7  | 11 |
| 4  | 2  | 4  | 8  | 23 |
| 5  | 4  | 5  | 4  | 11 |
| 6  | 5  | 6  | 5  | 22 |
| 7  | 6  | 4  | 3  | 23 |
| 8  | 5  | 5  | 4  | 31 |
| 9  | 6  | 6  | 3  | 22 |
| 10 | 6  | 7  | 6  | 16 |
| 11 | 7  | 7  | 6  | 25 |
| 12 | 8  | 8  | 8  | 33 |

Predicted

Y-pred

31

## K: Fold cross validation, example K = 4

Training data

Test on 4

| No | X1 | X2 | X3 | Y  |
|----|----|----|----|----|
| 1  | 4  | 9  | 4  | 20 |
| 2  | 8  | 4  | 6  | 11 |
| 3  | 1  | 5  | 7  | 12 |
| 4  | 3  | 3  | 7  | 11 |
| 4  | 2  | 4  | 8  | 23 |
| 5  | 4  | 5  | 4  | 11 |
| 6  | 5  | 6  | 5  | 22 |
| 7  | 6  | 4  | 3  | 23 |
| 8  | 5  | 5  | 4  | 31 |
| 9  | 6  | 6  | 3  | 22 |
| 10 | 6  | 7  | 6  | 16 |
| 11 | 7  | 7  | 6  | 25 |
| 12 | 8  | 8  | 8  | 33 |

Predicted

| Y-pred |
|--------|
|        |

|        |
| 20     |
| 18     |
| 24     |
| 31     |

# Train/Test Split (Regression)

- Split data into Training (learn) and Testing (check).
- Train model on 70% of the data, test it on 30%.
- Test results show how model works on unseen data.

## Split data into Training (learn) and Testing (check)

Training data

Test data

| No | X1 | X2 | X3 | Y  |
|----|----|----|----|----|
| 1  | 4  | 9  | 4  | 20 |
| 2  | 8  | 4  | 6  | 11 |
| 3  | 1  | 5  | 7  | 12 |
| 4  | 3  | 3  | 7  | 11 |
| 4  | 2  | 4  | 8  | 23 |
| 5  | 4  | 5  | 4  | 11 |
| 6  | 5  | 6  | 5  | 22 |
| 7  | 6  | 4  | 3  | 23 |
| 8  | 5  | 5  | 4  | 31 |

# Regression metrics

- **Regression** = predicting numbers (like milk yield in l).
- We check:
  - **RMSE**: How far predictions are from the real value on average.
  - **MAE**: Average error without worrying about positive or negative.
  - **R<sup>2</sup>**: How much of the variation in results our model explains.
- Smaller RMSE/MAE is better.
- R<sup>2</sup> closer to 1 is better.

# RStudio

- Use the file:Performance\_regression.R

# Classification

# Classification

- **Classification** = predicting categories ("Low" or "High").
- We use logistic regression to estimate the probability of "High" yield.
- Then pick a **threshold** (often 0.5) to decide

# Train/Test Split (Classification)

- Same idea as regression but for "Low"/"High".
- Shows accuracy and other metrics for test data.
- Prevents overfitting (memorizing instead of learning).

# Calibration Plot

- Checks if predicted probabilities match reality.
- Example: If we say 70% chance of "High", does it really happen 7 out of 10 times?
- Good calibration means predictions are trustworthy.

# What is a Confusion Matrix?

- A 2×2 table comparing model predictions vs. actual labels for binary classification.
- Terminology
  - TP (True Positive): predicted High when actual High
  - FP (False Positive): predicted High when actual Low
  - FN (False Negative): predicted Low when actual High
  - TN (True Negative): predicted Low when actual Low
- All metrics below are computed from TP, FP, FN, TN.

# Confusion Matrix Layout

|              | Predicted: High | Predicted: Low |
|--------------|-----------------|----------------|
| Actual: High | TP              | FN             |
| Actual: Low  | FP              | TN             |

# Accuracy

- **Definition:** Proportion of all predictions that are correct.
- **Formula:**  $\text{Accuracy} = (TP + TN) / (TP + FP + FN + TN)$
- Use when
  - Classes are roughly balanced and all errors have similar cost.
- Beware
  - Can be misleading on imbalanced data (e.g., 95% one class).

# Precision (Positive Predictive Value)

- **Definition:** Of all predicted High, how many are truly High?
- **Formula:**  $\text{Precision} = \text{TP} / (\text{TP} + \text{FP})$
- Use when
  - False positives are costly (e.g., flagging healthy animals as sick).

# Recall (Sensitivity, True Positive Rate)

- **Definition:** Of all actual High, how many did we correctly predict?
- Formula:  $\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$
- Use when
  - Missing positives is costly (e.g., failing to detect truly high-yield animals).

# Specificity (True Negative Rate)

- **Definition:** Of all actual Low, how many did we correctly predict?
- **Formula:**  $\text{Specificity} = \text{TN} / (\text{TN} + \text{FP})$
- **Related:** False Positive Rate (FPR) =  $1 - \text{Specificity}$ .

# Confusion Matrix Heatmap

- Visual version of confusion matrix.
- Darker colors = more cases.
- Easier to explain and spot patterns.

# Worked Example (Numbers)

- Example confusion matrix: TP = 40, FP = 10, FN = 20, TN = 30 (Total=100)
- Accuracy =  $(TP+TN)/\text{Total} = (40+30)/100 = 0.700$
- Precision =  $TP/(TP+FP) = 40/(40+10) = 0.800$
- Recall (Sensitivity) =  $TP/(TP+FN) = 40/(40+20) = 0.667$
- Specificity =  $TN/(TN+FP) = 30/(30+10) = 0.750$

# Calibration plot for test set

- Like in confusion matrix only using the test data.
- Visual version of confusion matrix.
- Darker colors = more cases.
- Easier to explain and spot patterns

# Receiver Operating Characteristic (ROC)

- ROC (Receiver Operating Characteristic) plots model performance across all thresholds.
- $x = \text{FPR} = \text{FP}/(\text{FP} + \text{TN})$ ,
- $y = \text{TPR (Recall)} = \text{TP}/(\text{TP} + \text{FN})$ .

# ROC

- **How it is built:** vary the classification threshold on predicted scores/probabilities.
- **AUC (Area Under Curve):**  $0.5 \approx$  random,  $1.0 =$  perfect; higher is better, threshold-independent.
- **Interpretation:** curves closer to the top-left are better; diagonal is random guessing.
- **Use cases:** compare classifiers and choose operating points; for rare positives, also check PR curves.

# Receiver Operating Characteristics Curve (ROC)

- Shows trade-off between True Positives and False Positives.
- AUC (Area Under Curve) closer to 1 = better model.
- ROC helps choose the right threshold.

# Precision-Recall Curve

- Focuses on "High" predictions.
- Precision = out of all predicted "High", how many are correct?
- Recall = out of all real "High", how many did we find?

# Threshold Sweep

- Shows how Accuracy, Precision, Recall, Specificity, and F1 change as the threshold moves from 0 to 1.
- Helps pick the best threshold for the situation.
